

Ecoregions of Tennessee

- 65 Southeastern Plains
- 65a Blackland Prairies
- 65b Flatwoods/Alluvial Prairie Margins
- 65c Southern Plains and Hills
- 65d Fall Line Hills
- 65e Transition Hills
- 66 Blue Ridge Mountains
- 66a Southern Ridges and Mountains
- 66b Southern Sedimentary Ridges
- 66c Southern Metasedimentary Mountains
- 67 Ridge and Valley
- 67a Southern Limestone-Dolomite Valleys and Low Rolling Hills
- 67b Southern Sandstone Ridges
- 67c Southern Sandstone Ridges and Knobs
- 67d Western Pennsylvanian Karst
- 67e Western Highland Rim
- 67f Eastern Highland Rim
- 67g Outer Nashville Basin
- 67h Inner Nashville Basin
- 68 Southwestern Appalachians
- 68a Cumberland Mountains
- 68b Limestone Valleys and Coves
- 68c Scapulate Valley
- 68d Plateau Escarpment
- 69 Central Appalachians
- 69a Cumberland Mountains
- 70 Interior Plateau
- 71a Northern Mississippi Alluvial Plain
- 71b Mississippi Valley Loess Plains
- 71c Loess Plains

Ecoregions denote areas of general similarity in ecosystems and in the type, quality, and quantity of environmental resources; they are designed to serve as a useful framework for the research, assessment, management, and monitoring of ecosystems and ecosystem components. Ecoregions are directly applicable to the immediate needs of state agencies, such as the Tennessee Department of Environment and Conservation (TDEC), for defining regional natural resource areas and identifying high-quality waters, developing ecoregion-specific chemical and biological water quality criteria and standards, and implementing TDEC's watershed management program. Ecoregion frameworks are also relevant to integrated ecosystem management, a shared goal of most federal and state resource management agencies.

The approach used to compile this atlas is based on the premise that ecological regions can be identified through the analysis of the patterns and the composition of biotic and abiotic phenomena that affect or reflect differences in ecosystems quality and integrity (Wilson 1986, Omernik 1975). The relative importance of each characteristic varies from one ecological region to another regardless of the hierarchical level. A Raman number (Raman 1984) has been assigned for each region to indicate differences between levels of ecological regions. Level I is the coarsest level, dividing North America into 15 ecological regions, with level II subdividing the continent into 52 regions. At level III, the continental United States is contained in 99 regions. The Tennessee Environmental Protection Agency (USEPA 1997), Level IV is a further subdivision of Level III ecoregions. Evolution of the methods used to define USEPA's ecoregions are given in Omernik (1995), Griffith et al. (1994, 1997), and Callan et al. (1995).

This Level III and IV ecoregion map was compiled at a scale of 1:200,000; it depicts revisions and subdivisions of earlier Level III ecoregions that were originally compiled at a smaller scale (USEPA 1996, Omernik 1975). The poster is part of a collaborative project primarily between the USEPA National Health and Environmental Effects Research Laboratory - Corvallis, OR, and TDEC's Division of Water Pollution Control. Collaboration and consultation also occurred with the United States Department of Agriculture - Natural Resources Conservation Service (NRCS), the United States Department of Agriculture - Forest Service (USFS), USEPA Region IV, and with other State of Tennessee agencies.

This project is associated with an integrative effort to develop a common framework of ecological regions. Reaching that objective requires recognition of the differences in the conceptual approaches and mapping methodologies that have been used to develop the most commonly used ecoregion frameworks, including those prepared by the USEPA (Bullard et al. 1994), the USEPA (Omernik 1975, 1995), and the NRCS (U.S. Department of Agriculture 1981). As each of these frameworks is further developed, the differences between them lessen. Regional collaborative projects such as this one in Tennessee, where some agreement can be reached among multiple resource management agencies, is a step in the direction of attaining consistency in ecoregion frameworks for the entire nation.

65. Southeastern Plains
 Three irregular plains have a mosaic of cropland, pasture, woodland, and oak-hickory-pine forest. The Centronas of Tertiary-age sands, silts, and clays of the region contrast geologically with the older limestone, chert, and shale found in the Interior Plateau (71). Elevation ranges from 200 to 600 feet, but generally lies in the Interior Plateau (71) to the east. Streams in this area are relatively low-gradient and sand-bottomed.

65a. The Blackland Prairie, extending north from Mississippi, is a flat to undulating piedmont region covering only a small portion of Missouri, Tennessee, Georgia, and Alabama. Although there is some of the Centronas-type chalk, marl, and calcareous clay that characterizes the region in Missouri and Alabama, the northern extent of the Blackland Prairie in Tennessee is not distinct. To the south, the natural vegetation had dominant trees of oaks, hickories, pine oak, and cypress, along with patches of Missouri prairie. Today, the area is mostly in cropland and pasture, with small patches of mixed hardwood forest.

65b. The Flatwoods/Alluvial Prairie Margins extend north from Mississippi, but the discontinuous of these narrow ecoregions fall quickly from Ripley, Mississippi northward. In Mississippi and Alabama, this is a transition region between the Blackland Prairie and the more rolling hills and ridges to the east. In the Flatwoods area, impurities are heavily forested, but the prairie and alluvial areas now have significant amounts of cropland and pasture. In Tennessee, the small region stands out as a highly agricultural land compared to the Interior Southeastern Plains and Hills (65c) that surround it.

65c. The Southeastern Plains and Hills contain several north-south trending bands of soil and clay formations. Tertiary-age sand, silt, and lignite are to the east, and Centronas-age fine sand, fossiliferous limestone sand, and silt clay are to the west. With

elevation reaching over 600 feet, and more rolling topography and more relief than the Loess Plains (70) to the east, streams have increased potential, generally sandy substrates, and distinctive fauna characteristics for west Tennessee. The natural vegetation type is oak-hickory forest, grading into oak-hickory-pine to the south.

65d. The Fall Line Hills comprise, comprising the Tennessee and Tuckahoe Hills in Alabama, and the Fall Line Hills in Alabama. It is composed primarily of Centronas-age coastal plain sandstone, limestone, and thin chert gravel-surfaced materials are covered by sandy loam topsoils. It is mostly forested trees of oak-hickory-pine on open hills, with 100-200 feet of relief. Elevation in the small Tennessee portion, except between Chambers Creek and Pawlick Lake in Hardin County, are 450-685 feet.

65e. The Transition Hills have the highest elevations in Ecoregion 65, and contain characteristics of both the Southeastern Plains and the Interior Plateau (71) ecoregions. Many streams of this transition area flow on down into the Mississippi, Devonian, and Silurian-age rocks and may look similar to those of the Interior Plateau (71). Centronas-age coastal plain deposits of silt, clay, and gravel, however, overlie the older limestone, shale, and chert. It is a mostly forested region of oak-hickory-pine, and has had pine plantation activities associated with pulp and paper operations.

View of Centronas Hill, a rolling prairie and from Brown, Tennessee. The Fall Line Hills and the Fall Line Hills. The Fall Line Hills are composed primarily of Centronas-age coastal plain sandstone, limestone, and thin chert gravel-surfaced materials are covered by sandy loam topsoils. It is mostly forested trees of oak-hickory-pine on open hills, with 100-200 feet of relief. Elevation in the small Tennessee portion, except between Chambers Creek and Pawlick Lake in Hardin County, are 450-685 feet.

66. Blue Ridge Mountains
 The Blue Ridge Mountains of Tennessee are forested slopes, high gradient, cool, clear streams, and rugged terrain on a mix of igneous, metamorphic, and sedimentary geology. Annual precipitation of nearly 60 inches can occur on the west-sloping high peaks of the Great Smoky Mountains that reach over 6000 feet. The southern Blue Ridge is one of the most ecoregions of biodiversity in the eastern U.S. It is the most floristically diverse ecoregion of the state, and includes Appalachian oak forest, northern hardwood, and Southeastern spruce-fir forest. Shad, grass, and health beds, hemlock, cork hardwoods, and oak-pine communities are also significant.

66a. The Southern Ridges and Mountains occur in Tennessee's northeastern corner. The Blue Ridge Mountains of Tennessee are forested slopes, high gradient, cool, clear streams, and rugged terrain on a mix of igneous, metamorphic, and sedimentary geology. Annual precipitation of nearly 60 inches can occur on the west-sloping high peaks of the Great Smoky Mountains that reach over 6000 feet. The southern Blue Ridge is one of the most ecoregions of biodiversity in the eastern U.S. It is the most floristically diverse ecoregion of the state, and includes Appalachian oak forest, northern hardwood, and Southeastern spruce-fir forest. Shad, grass, and health beds, hemlock, cork hardwoods, and oak-pine communities are also significant.

66b. The Southern Sedimentary Ridges in Tennessee include some of the westernmost high-grade metamorphic rocks. The typical crystalline rock types include granite, gneiss, schist, and amphibolite. The rocks are generally Cambrian-age sedimentary (shale, sandstone, siltstone, quartzite, conglomerate), although some lower stream reaches occur on limestone. Soils are predominantly friable loams and fine sandy loams with variable amounts of sandstone rock fragments, and support mostly mixed oak and oak-pine forests.

66c. Limestone Valleys and Coves are small but distinct lowland areas of the Blue Ridge, with elevations mostly between 1500 and 2500 feet. About 450 million years ago, older Blue Ridge rocks to the east were forced up and over younger rocks to the west.

In places, the Precambrian rocks have eroded through to Cambrian or Ordovician-age limestones, or even especially in isolated, steep areas that are surrounded by Southeastern limestones. The main areas of limestone include the Mountain City area and Shady Valley to the north, and West Cove, Tuckahoe Cove, and Cash Cove of the Great Smoky Mountains in the south. Hay and pasture, with some tobacco patches on small farms, are typical land uses.

66d. The Southern Metasedimentary Mountains are steep, dissected, biologically diverse mountains that include Cades Cove (2064 feet), the highest point in the four-state region of metamorphic and sedimentary rocks in the Blue Ridge. This region is generally older and more metamorphosed than the Southern Sedimentary Ridge (66b) to the west and east. The Appalachian oak forest, and higher elevations, the northern hardwoods forest, include a variety of oak and pines, as well as sycamore, hemlock, yellow poplar, basswood, beeches, yellow birch, and hickory. Spruce-fir forests, found generally above 5500 feet, have been affected greatly over the past twenty-five years by the balsam woolly adelg. The Copper Basin, in the southeast corner of Tennessee, was the site of copper mining and smelting from the 1850's to 1987, and once left more than fifty square miles of eroded bare earth.

View of the Blue Ridge Mountains in Tennessee. The Blue Ridge Mountains of Tennessee are forested slopes, high gradient, cool, clear streams, and rugged terrain on a mix of igneous, metamorphic, and sedimentary geology. Annual precipitation of nearly 60 inches can occur on the west-sloping high peaks of the Great Smoky Mountains that reach over 6000 feet. The southern Blue Ridge is one of the most ecoregions of biodiversity in the eastern U.S. It is the most floristically diverse ecoregion of the state, and includes Appalachian oak forest, northern hardwood, and Southeastern spruce-fir forest. Shad, grass, and health beds, hemlock, cork hardwoods, and oak-pine communities are also significant.

67. Ridge and Valley
 Also known as the Great Valley of Tennessee, this is a relatively low-lying region between the Blue Ridge Mountains to the east and the Cumberland Plateau to the west. As a result of extensive folding and faulting, valleys occur in a variety of widths, heights, and geologic materials, including limestone, dolomite, shale, sandstone, chert, limestone, and marble. Springs and coves are relatively numerous. Present-day forests cover about 50% of the region. The ecoregion has great aquatic habitat diversity in streams and supports a diverse fish community.

67a. The Southern Limestone-Dolomite Valleys and Low Rolling Hills form a heterogeneous region composed predominantly of limestone and chert dolomite. The region is mostly low-lying, with elevations generally less than 1000 feet. Productivity is low to moderate, but the region is rich in biodiversity. Landcover includes intensive agriculture, urban and industrial, or areas of thick forest with some sandstone, chert, and limestone. The region is rich in biodiversity for the same reasons: types, and grassland habitats interspersed with oak-pine forest.

67b. The Southern Shale Valleys consist of lowlands, rolling valleys, and slopes and hills. Shale areas are dominated by shale materials. The northern valleys are associated with the Southern Sedimentary Ridges, and often slightly west to north. In the south, the shale valleys are associated with Cambrian geology that contains some sandstone, chert, and limestone. The region is rich in biodiversity for the same reasons: types, and grassland habitats interspersed with oak-pine forest.

67c. The Southern Sandstone Ridges and Knobs consist of lowlands, rolling valleys, and slopes and hills. Sandstone areas are dominated by sandstone materials. The northern valleys are associated with the Southern Sedimentary Ridges, and often slightly west to north. In the south, the sandstone ridges are associated with Cambrian geology that contains some sandstone, chert, and limestone. The region is rich in biodiversity for the same reasons: types, and grassland habitats interspersed with oak-pine forest.

ridges have narrow crests, and the soils are typically sandy, and of low fertility. The chemistry of streams flowing down the ridges can vary greatly depending on the geologic material. The higher elevation ridges are in the north, including Waller Ridge, Powell Mountain, Clinch Mountain and Bay Mountain. White Oak Mountain in the south has some sandstone on the north side, but abundant shale and limestone. Granddove Mountain, capped by the Cretaceous Group sandstone, is the only remnant of Pennsylvanian-age strata in the Ridge and Valley ecoregion.

67d. The Southern Dissected Ridges and Knobs consist of more eroded, knoblike, and knobby ridges, compared to the smoother, more sharply pointed sandstone ridges of Ecoregion 67b. Although not as common, there is a mixture of sandstone and geologic materials. The ridges on the east side of Tennessee's Ridge and Valley tend to be associated with the Ordovician-age shale, sandstone, and limestone. Granddove Mountain, capped by the Cretaceous Group sandstone, is the only remnant of Pennsylvanian-age strata in the Ridge and Valley ecoregion.

67e. The Southern Dissected Ridges and Knobs consist of more eroded, knoblike, and knobby ridges, compared to the smoother, more sharply pointed sandstone ridges of Ecoregion 67b. Although not as common, there is a mixture of sandstone and geologic materials. The ridges on the east side of Tennessee's Ridge and Valley tend to be associated with the Ordovician-age shale, sandstone, and limestone. Granddove Mountain, capped by the Cretaceous Group sandstone, is the only remnant of Pennsylvanian-age strata in the Ridge and Valley ecoregion.

Springs and coves are relatively numerous. Present-day forests cover about 50% of the region. The ecoregion has great aquatic habitat diversity in streams and supports a diverse fish community.

68. Southwestern Appalachians
 Stretching from Kentucky to Tennessee, these open low mountains consist of a mosaic of forest and woodland with only slightly more oak than the Interior Plateau (71). It is relatively more oak and only slightly more oak than the Interior Plateau (71). It is relatively more oak and only slightly more oak than the Interior Plateau (71). It is relatively more oak and only slightly more oak than the Interior Plateau (71).

68a. The Cumberland Plateau's suballuvial and open low mountains are about 1000 feet higher than the Eastern Highland Rim (71e) to the west, and receive slightly more precipitation. The plateau surface is low dissected with relief compared to the Interior Plateau (71). The region is forested, with some agriculture and cool montane forests. The plateau surface is low dissected with relief compared to the Interior Plateau (71). The region is forested, with some agriculture and cool montane forests.

68b. The Plateau Escarpment is characterized by steep, forested slopes and high, rocky hills. The region is forested, with some agriculture and cool montane forests. The plateau surface is low dissected with relief compared to the Interior Plateau (71). The region is forested, with some agriculture and cool montane forests.

68c. The Scapulate Valley is structurally associated with an anticline, where erosion of limestone rock to the south of the Crab Orchard Mountains separated the linear valley from the rest of the Cumberland Plateau. A low, central, cherty ridge occurs below the top of the Cumberland Plateau. A low, central, cherty ridge occurs below the top of the Cumberland Plateau.

the Interior Plateau (71). It is relatively more oak and only slightly more oak than the Interior Plateau (71). It is relatively more oak and only slightly more oak than the Interior Plateau (71). It is relatively more oak and only slightly more oak than the Interior Plateau (71).

68d. The Plateau Escarpment is characterized by steep, forested slopes and high, rocky hills. The region is forested, with some agriculture and cool montane forests. The plateau surface is low dissected with relief compared to the Interior Plateau (71). The region is forested, with some agriculture and cool montane forests.

68e. The Scapulate Valley is structurally associated with an anticline, where erosion of limestone rock to the south of the Crab Orchard Mountains separated the linear valley from the rest of the Cumberland Plateau. A low, central, cherty ridge occurs below the top of the Cumberland Plateau. A low, central, cherty ridge occurs below the top of the Cumberland Plateau.

Stretching from Kentucky to Tennessee, these open low mountains consist of a mosaic of forest and woodland with only slightly more oak than the Interior Plateau (71). It is relatively more oak and only slightly more oak than the Interior Plateau (71). It is relatively more oak and only slightly more oak than the Interior Plateau (71).

69. Central Appalachians
 The Interior Plateau is a diverse ecoregion extending from southern Indiana and Ohio to northern Alabama. Rock types are distinctly different from the coastal plain sands of western Tennessee ecoregions, and elevations are lower than the Appalachian ecoregions to the east. Mississippi to Ordovician-age limestone, chert, sandstone, siltstone, and shale compose the foundations of open hills, irregular plains, and alluvial fans. The natural vegetation is primarily oak-hickory forest, with some area of limestone prairie and cedar glades. The region has the most diverse fish fauna in Tennessee.

69a. The Cumberland Mountains are composed of the western Highland Rim (71d), Sandhills and Depression are common. The productive soils of the mobile agricultural areas are formed mostly from a thin loess mantle over residual or Pennsylvanian-age limestones. Most of the region is cultivated as a pasture, tobacco and livestock are the principal agricultural products, with some corn, soybeans, and small grains. The natural vegetation consisted of oak-hickory forest with patches of bluestem prairie. The harem of Kentucky that extended south into Missouri, Montgomery and Robertson counties, were once some of the largest natural grasslands in Tennessee.

69b. The Western Pennsylvanian Karst is a flatter area of irregular plains, with lower to moderate elevations, with elevations of 400-1000 feet. The geologic base of Mississippian limestone, chert, and shale is covered by soils that tend to be cherty, acid, and low to moderate fertility. Streams are characterized by coarse chert gravel and sand substrates, with areas of bedrock, moderate gradients, and relatively slow flow. The oak-hickory natural vegetation was mostly deforested in the mid to late 1800's, in conjunction with the iron-ore related mining and smelting of the mineral basin, but now the region is again heavily forested. Some agriculture occurs on the flatter interfluves and in the stream and river valleys: mostly hay, pasture, and cattle, with some cultivation of corn and tobacco.

69c. The Eastern Highland Rim has lower elevations than the Western Highland Rim (71c), with landforms characterized as suballuvial of moderate relief and irregular plains. Mississippian-age limestone, chert, shale, and dolomite predominance and have terraces and depressions are especially noticeable between Sparta and McMinnville. Numerous springs and spring-associated fish fauna also typify the region. Natural vegetation for the region is transitional between the oak-hickory type to the west and the mixed mesophytic forests of the Appalachian ecoregion (68, 69b) to the east. Bottomland hardwood forests have been inundated by several large impoundments. Barren and former prairie areas are now mostly oak-hickory forest of pasture and cropland.

70. Interior Plateau
 The Interior Plateau is a diverse ecoregion extending from southern Indiana and Ohio to northern Alabama. Rock types are distinctly different from the coastal plain sands of western Tennessee ecoregions, and elevations are lower than the Appalachian ecoregions to the east. Mississippi to Ordovician-age limestone, chert, sandstone, siltstone, and shale compose the foundations of open hills, irregular plains, and alluvial fans. The natural vegetation is primarily oak-hickory forest, with some area of limestone prairie and cedar glades. The region has the most diverse fish fauna in Tennessee.

70a. The Western Pennsylvanian Karst is a flatter area of irregular plains, with lower to moderate elevations, with elevations of 400-1000 feet. The geologic base of Mississippian limestone, chert, and shale is covered by soils that tend to be cherty, acid, and low to moderate fertility. Streams are characterized by coarse chert gravel and sand substrates, with areas of bedrock, moderate gradients, and relatively slow flow. The oak-hickory natural vegetation was mostly deforested in the mid to late 1800's, in conjunction with the iron-ore related mining and smelting of the mineral basin, but now the region is again heavily forested. Some agriculture occurs on the flatter interfluves and in the stream and river valleys: mostly hay, pasture, and cattle, with some cultivation of corn and tobacco.

70b. The Eastern Highland Rim has lower elevations than the Western Highland Rim (71c), with landforms characterized as suballuvial of moderate relief and irregular plains. Mississippian-age limestone, chert, shale, and dolomite predominance and have terraces and depressions are especially noticeable between Sparta and McMinnville. Numerous springs and spring-associated fish fauna also typify the region. Natural vegetation for the region is transitional between the oak-hickory type to the west and the mixed mesophytic forests of the Appalachian ecoregion (68, 69b) to the east. Bottomland hardwood forests have been inundated by several large impoundments. Barren and former prairie areas are now mostly oak-hickory forest of pasture and cropland.

71. Mississippi Alluvial Plain
 The ecoregion extends from the Ohio River to western Kentucky to Louisiana. It consists primarily of irregular plains, with oak-hickory and oak-hickory-pine natural vegetation. Thick loess tends to be the distinguishing characteristic. With flatter topography than the Southeastern Plains (65) to the east, streams tend to have lower gradient and more silt and sand. The region has the most diverse fish fauna in Tennessee.

71a. The Northern Mississippi Alluvial Plain within Tennessee is a relatively flat, fertile region of Quaternary alluvial deposits of sand, silt, clay, and gravel. It is bounded directly to the east by the Blue Hill Hills (74a), and to the west by the Mississippi River. Average elevation is 200-300 feet with little relief. Most of the region is in cropland, with some areas of oak-hickory forest. Soybeans, corn, sorghum, and vegetables are the main crops. The natural vegetation consists of Southern Floodplain forest types, bald cypress, and magnolia. The region has the most diverse fish fauna in Tennessee.

71b. The Southern Mississippi Alluvial Plain within Tennessee is a relatively flat, fertile region of Quaternary alluvial deposits of sand, silt, clay, and gravel. It is bounded directly to the east by the Blue Hill Hills (74a), and to the west by the Mississippi River. Average elevation is 200-300 feet with little relief. Most of the region is in cropland, with some areas of oak-hickory forest. Soybeans, corn, sorghum, and vegetables are the main crops. The natural vegetation consists of Southern Floodplain forest types, bald cypress, and magnolia. The region has the most diverse fish fauna in Tennessee.

71c. The Northern Mississippi Alluvial Plain within Tennessee is a relatively flat, fertile region of Quaternary alluvial deposits of sand, silt, clay, and gravel. It is bounded directly to the east by the Blue Hill Hills (74a), and to the west by the Mississippi River. Average elevation is 200-300 feet with little relief. Most of the region is in cropland, with some areas of oak-hickory forest. Soybeans, corn, sorghum, and vegetables are the main crops. The natural vegetation consists of Southern Floodplain forest types, bald cypress, and magnolia. The region has the most diverse fish fauna in Tennessee.

71d. The Southern Mississippi Alluvial Plain within Tennessee is a relatively flat, fertile region of Quaternary alluvial deposits of sand, silt, clay, and gravel. It is bounded directly to the east by the Blue Hill Hills (74a), and to the west by the Mississippi River. Average elevation is 200-300 feet with little relief. Most of the region is in cropland, with some areas of oak-hickory forest. Soybeans, corn, sorghum, and vegetables are the main crops. The natural vegetation consists of Southern Floodplain forest types, bald cypress, and magnolia. The region has the most diverse fish fauna in Tennessee.

72. Mississippi Valley Loess Plains
 The Blue Hill Hills consist of sand, clay, silt, and lignite, and are capped by loess. The Blue Hill Hills are generally more dissected, and forested. The carved hills have a mosaic of microenvironments, including dry slopes and ridges, moist slopes, riparian, bottomland areas, and small cypress swamps. While oak-hickory is the general forest type, some of the undisturbed bluff vegetation is rich in mesophytes, such as beech and sugar maple, with similarities to hardwood forests of eastern Tennessee. Smaller streams of the Blue Hill Hills have localized reaches of increased gradient and small areas of forest substrate that create aquatic habitats that are distinct from those of the Loess Plains (71b) to the east. Unusual, isolated fish assemblages more typical of riparian habitats can be found in these stream reaches. Crawfish are also reported in places at the base of the bluffs.

73. Mississippi Alluvial Plain
 The ecoregion extends from the Ohio River to western Kentucky to Louisiana. It consists primarily of irregular plains, with oak-hickory and oak-hickory-pine natural vegetation. Thick loess tends to be the distinguishing characteristic. With flatter topography than the Southeastern Plains (65) to the east, streams tend to have lower gradient and more silt and sand. The region has the most diverse fish fauna in Tennessee.

73a. The Northern Mississippi Alluvial Plain within Tennessee is a relatively flat, fertile region of Quaternary alluvial deposits of sand, silt, clay, and gravel. It is bounded directly to the east by the Blue Hill Hills (74a), and to the west by the Mississippi River. Average elevation is 200-300 feet with little relief. Most of the region is in cropland, with some areas of oak-hickory forest. Soybeans, corn, sorghum, and vegetables are the main crops. The natural vegetation consists of Southern Floodplain forest types, bald cypress, and magnolia. The region has the most diverse fish fauna in Tennessee.

73b. The Southern Mississippi Alluvial Plain within Tennessee is a relatively flat, fertile region of Quaternary alluvial deposits of sand, silt, clay, and gravel. It is bounded directly to the east by the Blue Hill Hills (74a), and to the west by the Mississippi River. Average elevation is 200-300 feet with little relief. Most of the region is in cropland, with some areas of oak-hickory forest. Soybeans, corn, sorghum, and vegetables are the main crops. The natural vegetation consists of Southern Floodplain forest types, bald cypress, and magnolia. The region has the most diverse fish fauna in Tennessee.

74. Mississippi Valley Loess Plains
 The Blue Hill Hills consist of sand, clay, silt, and lignite, and are capped by loess. The Blue Hill Hills are generally more dissected, and forested. The carved hills have a mosaic of microenvironments, including dry slopes and ridges, moist slopes, riparian, bottomland areas, and small cypress swamps. While oak-hickory is the general forest type, some of the undisturbed bluff vegetation is rich in mesophytes, such as beech and sugar maple, with similarities to hardwood forests of eastern Tennessee. Smaller streams of the Blue Hill Hills have localized reaches of increased gradient and small areas of forest substrate that create aquatic habitats that are distinct from those of the Loess Plains (71b) to the east. Unusual, isolated fish assemblages more typical of riparian habitats can be found in these stream reaches. Crawfish are also reported in places at the base of the bluffs.

74a. The Blue Hill Hills consist of sand, clay, silt, and lignite, and are capped by loess. The Blue Hill Hills are generally more dissected, and forested. The carved hills have a mosaic of microenvironments, including dry slopes and ridges, moist slopes, riparian, bottomland areas, and small cypress swamps. While oak-hickory is the general forest type, some of the undisturbed bluff vegetation is rich in mesophytes, such as beech and sugar maple, with similarities to hardwood forests of eastern Tennessee. Smaller streams of the Blue Hill Hills have localized reaches of increased gradient and small areas of forest substrate that create aquatic habitats that are distinct from those of the Loess Plains (71b) to the east. Unusual, isolated fish assemblages more typical of riparian habitats can be found in these stream reaches. Crawfish are also reported in places at the base of the bluffs.

74b. The Loess Plains are generally rolling irregular plains, 250-500 feet in elevation, with loess up to 50 feet thick. The region is a productive agricultural area of oak-hickory, bottomland areas, and small cypress swamps. While oak-hickory is the general forest type, some of the undisturbed bluff vegetation is rich in mesophytes, such as beech and sugar maple, with similarities to hardwood forests of eastern Tennessee. Smaller streams of the Blue Hill Hills have localized reaches of increased gradient and small areas of forest substrate that create aquatic habitats that are distinct from those of the Loess Plains (71b) to the east. Unusual, isolated fish assemblages more typical of riparian habitats can be found in these stream reaches. Crawfish are also reported in places at the base of the bluffs.

74c. The Loess Plains are generally rolling irregular plains, 250-500 feet in elevation, with loess up to 50 feet thick. The region is a productive agricultural area of oak-hickory, bottomland areas, and small cypress swamps. While oak-hickory is the general forest type, some of the undisturbed bluff vegetation is rich in mesophytes, such as beech and sugar maple, with similarities to hardwood forests of eastern Tennessee. Smaller streams of the Blue Hill Hills have localized reaches of increased gradient and small areas of forest substrate that create aquatic habitats that are distinct from those of the Loess Plains (71b) to the east. Unusual, isolated fish assemblages more typical of riparian habitats can be found in these stream reaches. Crawfish are also reported in places at the base of the bluffs.

74d. The Loess Plains are generally rolling irregular plains, 250-500 feet in elevation, with loess up to 50 feet thick. The region is a productive agricultural area of oak-hickory, bottomland areas, and small cypress swamps. While oak-hickory is the general forest type, some of the undisturbed bluff vegetation is rich in mesophytes, such as beech and sugar maple, with similarities to hardwood forests of eastern Tennessee. Smaller streams of the Blue Hill Hills have localized reaches of increased gradient and small areas of forest substrate that create aquatic habitats that are distinct from those of the Loess Plains (71b) to the east. Unusual, isolated fish assemblages more typical of riparian habitats can be found in these stream reaches. Crawfish are also reported in places at the base of the bluffs.

View of the Mississippi Valley Loess Plains in Tennessee. The Blue Hill Hills consist of sand, clay, silt, and lignite, and are capped by loess. The Blue Hill Hills are generally more dissected, and forested. The carved hills have a mosaic of microenvironments, including dry slopes and ridges, moist slopes, riparian, bottomland areas, and small cypress swamps. While oak-hickory is the general forest type, some of the undisturbed bluff vegetation is rich in mesophytes, such as beech and sugar maple, with similarities to hardwood forests of eastern Tennessee. Smaller streams of the Blue Hill Hills have localized reaches of increased gradient and small areas of forest substrate that create aquatic habitats that are distinct from those of the Loess Plains (71b) to the east. Unusual, isolated fish assemblages more typical of riparian habitats can be found in these stream reaches. Crawfish are also reported in places at the base of the bluffs.

65. Southeastern Plains
 Three irregular plains have a mosaic of cropland, pasture, woodland, and oak-hickory-pine forest. The Centronas of Tertiary-age sands, silts, and clays of the region contrast geologically with the older limestone, chert, and shale found in the Interior Plateau (71). Elevation ranges from 200 to 600 feet, but generally lies in the Interior Plateau (71) to the east. Streams in this area are relatively low-gradient and sand-bottomed.

65a. The Blackland Prairie, extending north from Mississippi, is a flat to undulating piedmont region covering only a small portion of Missouri, Tennessee, Georgia, and Alabama. Although there is some of the Centronas-type chalk, marl, and calcareous clay that characterizes the region in Missouri and Alabama, the northern extent of the Blackland Prairie in Tennessee is not distinct. To the south, the natural vegetation had dominant trees of oaks, hickories, pine oak, and cypress, along with patches of Missouri prairie. Today, the area is mostly in cropland and pasture, with small patches of mixed hardwood forest.

65b. The Flatwoods/Alluvial Prairie Margins extend north from Mississippi, but the discontinuous of these narrow ecoregions fall quickly from Ripley, Mississippi northward. In Mississippi and Alabama, this is a transition region between the Blackland Prairie and the more rolling hills and ridges to the east. In the Flatwoods area, impurities are heavily forested, but the prairie and alluvial areas now have significant amounts of cropland and pasture. In Tennessee, the small region stands out as a highly agricultural land compared to the Interior Southeastern Plains and Hills (65c) that surround it.

65c. The Southeastern Plains and Hills contain several north-south trending bands of soil and clay formations. Tertiary-age sand, silt, and lignite are to the east, and Centronas-age fine sand, fossiliferous limestone sand, and silt clay are to the west. With

66. Blue Ridge Mountains
 The Blue Ridge Mountains of Tennessee are forested slopes, high gradient, cool, clear streams, and rugged terrain on a mix of igneous, metamorphic, and sedimentary geology. Annual precipitation of nearly 60 inches can occur on the west-sloping high peaks of the Great Smoky Mountains that reach over 6000 feet. The southern Blue Ridge is one of the most ecoregions of biodiversity in the eastern U.S. It is the most floristically diverse ecoregion of the state, and includes Appalachian oak forest, northern hardwood, and Southeastern spruce-fir forest. Shad, grass, and health beds, hemlock, cork
